

[ELZK - 004]

APPLICATION

FOR

UNITED STATES LETTERS PATENT

TO ALL WHOM IT MAY CONCERN:

Be it known that **John Kroeker and Oleg Boulanov** have invented a **WEB-BASED SPEECH RECOGNITION WITH SCRIPTING AND SEMANTIC OBJECTS**, of which the following description in connection with the accompanying drawings is a specification.

WEB-BASED SPEECH RECOGNITION WITH SCRIPTING AND SEMANTIC OBJECTS

FIELD OF THE INVENTION

The present invention generally relates to systems and methods for developing and implementing transactional speech applications. More specifically, the present invention relates to systems and methods for developing and implementing transactional speech applications using Web-based technologies.

CROSS REFERENCES TO RELATED APPLICATIONS

This application claims the benefit of priority from commonly owned U.S. Provisional Patent Application Serial Number 60/192,091, filed March 24 2000, entitled COMBINED SYNTACTIC AND SEMANTIC SEARCH, PARSING, AND APPLICATION ACCESS; U.S. Provisional Patent Application Serial Number 60/191,915, filed March 24 2000, entitled SPEECH RECOGNITION APPLICATION TECHNOLOGY USING WEB, SCRIPTING AND SEMANTIC OBJECTS; U.S. Provisional Patent Application Serial Number 60/192,090, filed March 24 2000, entitled A NOVEL APPROACH TO SPEECH RECOGNITION; and U.S. Provisional Patent Application Serial Number 60/192,076, filed March 24 2000, entitled REMOTE SERVER OBJECT ARCHITECTURE FOR SPEECH RECOGNITION.

This application is also related to the following co-pending U.S. patent applications, the contents of which are incorporated herein in their entirety by reference:

BACKGROUND OF THE INVENTION

With the proliferation of computer systems, an increasing amount of processing is becoming automated. At the same time, the processing power of such systems continues to evolve. To make use of this increasingly available processing capability, organizations are attempting to migrate functions historically performed by individuals, if at all, to automated systems. For instance, increasingly, computer systems are developed and used to engage humans via speech interaction. Some systems, as an example, are implemented to conduct interviews or surveys of individuals via a telephone, while other systems may interact with individuals without the use of a network. Additionally, as speech over the World Wide Web (the "Web") and the Internet (e.g., voice over IP) becomes more and more commonplace, one can assume that human - computer speech based interaction will be increasingly conducted using that medium.

20

One typical example of human - computer speech based interaction is survey systems, wherein a computer conducts an automated speech based survey of an individual over a

telephone. In such a case, the survey system may have a scripted survey (i.e., series of questions) to be asked of the individual. The survey system may ask a first question, as a prompt, and await (e.g., for 5 seconds) a response by the individual. If the survey system does not receive a response, or receives a response that it can not interpret, the survey system may ask the question again or provide an instructional type of feedback. If the survey system receives a response that it can interpret, the survey system goes on to ask a next question or present a next prompt.

Such human - computer systems usually include an automatic speech recognition (ASR) system that converts incoming acoustic information into useful linguistic units, such as words or phrases. In a transactional ASR, for example one operating over a telephone network, there are a set of allowed words and phrases, which are defined by grammars. The process of sorting through the grammars for a particular word or phrase usage is referred to as syntactic search, wherein the words and their order are determined, typically based on probability. Such syntactic search subsystems typically evaluate a word using a fixed start point and a fixed end point, and process that data to determine the word with a related probability. However, this approach tends to be inefficient since the timeframe between start and end points may be adequate for some audio inputs, but inadequate for others, where some data beyond an endpoint may be cutoff and in other cases more time may be spent on a word than is required. Additionally, if not yielding results above a certain threshold probability, such systems may backtrack and continue to process the audio input to improve the phonetic estimates. Otherwise, the system may just put forth a best guess, albeit with low confidence.

In such systems, typically audio inputs, whether speech or background noise, are

processed as valid speech, for the most part. That is, such systems do not usually maintain sufficient contextual knowledge about the expected response to eliminate extraneous noises (or "barge in"). As a result, such systems may attempt to interpret such noises as speech, thereby producing a result having embedded errors or rejecting the result altogether.

5 Development of speech applications that utilize speech recognition (SR) systems, to create such human - computer systems, is generally an expensive, time-consuming effort that requires a multi-disciplinary team. The dominant approach to improving the ease of such application development has been to create Web-based applications using HTML extensions. For example VOXML, VoiceXML, and SpeechML are known types of extensions created specifically for SR systems. However, these approaches have been seriously limited in their ability to represent complex speech interactions, due to strong limitations in their coding power, as well as limitations on their control of, and access to, the underlying SR engines. That is, HTML is not a true programming language, but is rather a markup language. Therefore, it only provides a very limited framework, which is not particularly conducive to creating robust applications. Access to the speech recognition engines by such VoiceXML applications is limited by the bottlenecks of markup languages, such as the lack of programming language facilities, and fixed, predefined interfaces to the SR engine.

Such VoiceXML applications typically reside with a SR system on a voice portal (or gateway) that acts as a client to a Web server that provides back-end services to the VoiceXML application. The back-end services include standard Web services and, usually, custom software required by the VoiceXML application. For example, a back-end (i.e., server-side) product data servlet is typically included that is responsible for talking to back-end services,

including converting received replies into XML. A product presentation servlet is typically also included at the server-side. This servlet is used to put content in a format required by the VoiceXML application (or client). A repository of VoiceXML specific XSL templates resides at the back-end and defines the formats used by the product presentation servlet. A product
5 service is also provided at the back-end that manages the dissemination of product-related information, for example, to facilitate product browsing. And, a product database used by the various server-side servlets and services also resides at the back-end.

This approach of a strong reliance on back-end, server-side services is required with such VoiceXML applications, since VoiceXML applications are not, themselves, capable of delivering complex and robust functions.

SUMMARY OF THE INVENTION

The present invention is a system and method for creating and implementing transactional speech applications (SAs) using Web technologies, without reliance on server-side standard or custom services. A transactional speech application may be any application that requires interpretation of speech in conjunction with a speech recognition (SR) system, such as, for example, consumer survey applications or systems. A speech application in accordance with the present invention is represented within a Web page, as an application script that interprets semantic objects according to a context. Any commonly known scripting language can be used to write the application script, such as Jscript, PerlScript, and VBscript. The present invention is "Web-based" to the extent that it implements Web technologies, but it need not include or access the World Wide Web.

Ins A2 A SR system includes a SR platform and SR application program. The SR system serves as an interface or gateway between a user accessible network and an application system (i.e., source) that generates the Web page that includes the application script. The application script source may be local or remote or remote to the SR system. If the SR system is to access a remote application system, the SR system includes page address information (e.g., URLs) and may be configured to access the application system and download the Web page in response to an incoming call.

Ins A3 The SR platform may be, for example, a standard server having a network interface that facilitates receipt of audio information. The network interface may facilitate reception of audio information by any of a variety of a networks, such as telephone networks, cellular telephone networks, the Web, Internet, local area networks (LANs), wide area networks

2
3
4
5 (WANs), private networks, virtual private networks (VPNs), intranets, extranets, wireless networks, and the like, or some combination thereof. The SR system may be accessible by any one or more of a variety of devices capable of communicating audio information, such as telephone, cellular telephone, personal computer (PC), personal digital assistant (PDA) or other types of audio enabled devices.

need only be configured to use these standard ActiveX interface objects, so do not require special or custom interfaces. The ActiveX objects are local to the SR system and can be used with any application script presented or downloaded.

Ins AH An semantic interface to the SR application exposes the application script to the SR system. The semantic interface is written as an object that is local to the SR system, such as an ActiveX object. The semantic interface object includes standard HTML browser functionality, including tag processing, hyper references, and so forth. The semantic interface object also supports HTML extensions, such as Dialog, Play, and Record, as well as other known HTML extensions. If there are script tags residing on the Web page, the semantic interface loads a corresponding script engine. Since the semantic interface is coded as a high-level object interface, it need not be customized for the application script. Through the semantic interface object, the application script controls the SR system. For example, the application script can task the SR application to begin recognition, play back a file, play a prompt, and so on. Such tasking may be accomplished using standard object oriented design (OOD) calls and methods.

Ins AH The SR application functionality is configured to produce and return a context free set of semantic data representing all possible valid interpretations of a received audio input. That is, the SR system may be configured to perform syntactic and semantic processing using a common, root grammar or set of grammars to produce a semantic data representing a plurality of valid interpretations of a received audio input. The semantic data is represented in a semantic object (or objects) passed from the SR application to the application script. Each semantic object passes through the semantic interface to an evaluation interface of the application script. The evaluation interface can also be written as an ActiveX object, which

may serve as an evaluation (or interpretation) tool to the application script. The application script provides a context to the evaluation interface. The evaluation interface determines the a category as a function of the context and applies the category to the set of semantic data to obtain a specific interpretation of the set of semantic data, from all of the possible
5 interpretations. This specific result may be referred to as a linguistic result, representing a word, phrase, or values. Once the linguistic result is determined, the application script processes the result to determine its next action or prompt for the user.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other objects of this invention, the various features thereof, as well as the invention itself, may be more fully understood from the following description, when read together with the accompanying drawings, described:

5 FIG. 1 is a network architecture within which the present invention may be implemented;

FIG. 2 is a block diagram depicting the various elements of an implementation of a speech application and speech recognition system in accordance with the present invention; and

FIG. 3 is a flow chart depicting a method of the present invention.

For the most part, and as will be apparent when referring to the figures, when an item is used unchanged in more than one figure, it is identified by the same alphanumeric reference indicator in all figures.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The present invention is a system and method for creating and implementing transactional speech applications (SAs) using Web technologies, without reliance on server-side standard or custom services. A transactional speech application may be any application that requires interpretation of speech in conjunction with a speech recognition (SR) system, such as, for example, consumer survey applications or systems. A speech application in accordance with the present invention is represented within a Web page, as an application script that interprets semantic objects according to a context. Any commonly known scripting language can be used to write the application script, such as Jscript, PerlScript, and VBscript. The present invention is "Web-based" to the extent that it implements Web technologies, but it need not include or access the World Wide Web.

InSA The present invention may be implemented on any one or more of a variety of devices, networks, and architectures. FIG. 1A shows one possible architecture 100 on which the present invention may be implemented. A SR system 120 includes a SR application program hosted on a standard platform, such as SR server 122. One or more associated databases 124 includes the SR application and data, such as context free grammar databases. The SR system serves as an interface or gateway between a user accessible network 130 and an application system (i.e., source) that generates the Web page that includes the application script. The application source may be local or remote to the SR system. In fact, the application script source may also be hosted on server 122. In other embodiments, application code may be hosted on an application server 110, having an associated DB 112, that is coupled to the SR system via any one of a variety of standard networks 150. In yet other embodiments, the SR

system may service a variety of application sources, some of which may be local and others may be remote to the SR system. If the SR system is to access a remote application system, the SR system includes page address information (e.g., URLs) and may be configured to access the application system and download the Web page in response to an incoming call.

5 The SR system 120 may include a network interface that facilitates receipt of audio information by any of a variety of a networks, such as telephone networks, cellular telephone networks, the Web, Internet, local area networks (LANs), wide area networks (WANs), private networks, virtual private networks (VPNs), intranets, extranets, wireless networks, and the like, or some combination thereof. The SR system may be accessible by any one or more of a variety of devices 140 capable of communicating audio information. Such devices 140 may include, but are not limited to, a standard telephone (including cellular telephones) 142, a laptop computer 144, or a desktop computer 146, as well as other audio enabled devices (e.g., personal digital assistants, audio receivers, and application servers).

A speech application may be any interactive application that collects, provides, and/or shares information. As examples, in the present invention, a speech application and application script may be any of a group of interactive applications, including consumer survey applications; Web access applications; educational applications, including health education applications and computer-based lesson applications and testing applications; screening applications, including patient screening applications and consumer screening applications; 20 health risk assessment applications; monitoring applications, including health data monitoring applications and consumer preference monitoring applications; compliance applications, including applications that generate notifications of compliance related activities, including

notifications regarding health or product maintenance; test results applications, including applications that provide at least one of lab test results, standardized tests results, consumer product test results, and maintenance results; and linking applications, including applications that link two or more of the above applications.

5 Referring to FIG. 2, a block diagram 200 showing an implementation of the present invention is shown. The Web page 220, including the application script 222, may reside local to the SR system or may be downloaded from a transactional speech application system 110 via network 150. In any event, Web page 220 is loaded on SR system 120 (or a platform local to it), represented as Web page 220' with application script 222'. The functionality of the speech application is delivered to the SR system 120 from the application script 222' without the need for server-side application coding at an application server 110, as is necessary in systems using speech applications written in VoiceXML, for example. That is, all required application functionality is downloaded as part of the application script and executed with the SR system 120. Such functionality includes presenting user prompts, processing user responses, overall application session management, and interfacing with other available modules or facilities that provide functionality. Such prompts may include questions, like "Have you ever been to Aruba?" User responses include, for example, answers to such questions, e.g., "Hundred times!" Overall session management may include administering a survey that presents such prompts and processes such responses. Such functionality also includes functionality to control
20 SR system 120 and standard HTML and operating system functionality. Interfaces to such functionality are preferably written as standalone, reusable objects.

In the preferred embodiment, all of the interface objects used by application script 222'

conform to a standard interface model, such as ActiveX. That is, ActiveX objects 230 provide the application script 222' access to standard Web services. Therefore, application script 222' can easily access all of the inherent ActiveX capabilities of the operating system (e.g., messaging, database access, etc.) via these standard interfaces 230 using standard ActiveX controls. Using ActiveX interface objects 23 (i.e., standard, consistent objects) for accessing and controlling functions available to the application script 222' greatly eases the development and integration of such applications. Speech application in accordance with the present invention need only be configured to use these standard ActiveX interface objects 230, so do not require special or custom interfaces. The ActiveX objects 230 are local to the SR system and can be used with any application script presented to or loaded thereon.

A semantic interface, referred to as the "Teller" interface 240, exposes the application script 222' to the SR application 210. The Teller interface is written as an ActiveX object that is local to the SR system 210. The Teller interface object 210 includes standard HTML browser functionality, including tag processing, hyper references, and so forth. The Teller interface object 240 also supports HTML extensions, such as Dialog, Play, and Record, as well as other known HTML extensions. If there are script tags residing on the Web page, the Teller interface object 240 loads a corresponding script engine.

Since the Teller interface is coded as a high-level object interface, it need not be customized for the application script 222'. Rather, many instances of the Teller interface object 240 can be created, each serving one of a variety of application scripts. An instance of the Teller interface object 240 can be created in advance or upon an incoming call from device 140. Through the Teller interface object 240, application script 222' controls the SR

application 210, represented as arrow 242. For example, the application script can task the SR application to begin recognition, play back a file, play a prompt, and so on. Such tasking may be accomplished using standard object oriented design (OOD) calls and methods.

Teller interface object 240 can be further appreciated with respect to the following

5 pseudo code segment:

// Transaction Parameters

void SetTimeout(int time);

void SetBargeIn(boolean b);

void SetListenRatio(float confidence);

// Transaction Methods

ResultInterface Play(String file);

ResultInterface Say(String sentence);

ResultInterface Listen(String semanticObjectClass);

boolean Hangup();

INS A7 The SR application 210 functionality is configured to produce and return a context free set of semantic data representing all possible valid interpretations of a received audio input.

The SR system may be of the form described in commonly owned, co-pending application having the U.S. Patent Application Serial Number _____ (Attorney reference

20 ELZK-002), incorporated herein by reference. That is, the SR system 120 may be configured to perform syntactic and semantic processing using a common, root grammar or set of grammars to produce a semantic tree instance representing all possible valid interpretations of

A
a received audio stream. The semantic data is represented in a semantic object (or objects) 244 passed from the SR application 210 to the application script 222'. Each semantic object 244 passes through the Teller interface 240 to an evaluation interface 250 of the application script.

The evaluation interface 250 can also be written as an ActiveX object, which may serve
5 as an evaluation (or interpretation) tool to the application script 222'. The application script 222' provides a context to the evaluation interface 250. The evaluation interface 250 determines a category associated with the context and applies the category to the semantic objects 244 to obtain a specific interpretation of the set of semantic data, from all of the possible interpretations. This specific result may be referred to as a linguistic result, representing a word, phrase, or values. Once the linguistic result is determined, the application script 222' processes the result to determine its next action or prompt for the user. The evaluation interface 250 may be further appreciated with the following pseudo code segment.

```
ResultInterface {  
    String asCategory(String category);  
}
```

20
JWSA8 Categories are identified by their names. They specify the particular semantic interpretation required. Note that a semantic object 244 may capable of interpretation using any one of multiple valid categories. These categories control different semantic interpretations of the semantic object, depending on context. Collectively, the categories describe all possible valid interpretations of the semantic object. Because all contexts are

represented, this allows the semantic object to be used and re-used in a context-independent manner. Examples of Categories are: "number", "string", "digits", "car-model".

FIG. 3 provides a flowchart that may be implemented by the applications and objects for FIG. 2 by a transactional speech application in accordance with the present invention. The process begins, for example, with receipt of an audio input by device 140 via network 130. This audio input is received by the SR system in step 302. If the application script 222' has not already been downloaded to SR system 120, the application script 222' is downloaded from a source in step 304. With receipt of an audio input, the application script 222' tasks the SR system via controls 242 to, for example, interpret the audio input, in step 306.

By interpreting the audio input, the SR application 210 generates a context free semantic tree instance representing all possible valid interpretations of the audio input, which is represented as one or more semantic objects 244, in step 308. In step 310, the SR application 210 passes the semantic object(s) 244 to the application object 222' via the Teller interface 240. The Teller interface does not perform any substantive processing of the semantic object(s) 244. Rather, a semantic tree evaluator 250 receives the semantic tree instance and a context dictated by the application script, in step 312. Evaluator 250 may be provided with the context by the application script 222' prior to receipt of the semantic tree instance, embodied in semantic object 244. The semantic tree instance may be directly received from the SR application 210 or it may be passed through the application script 222', depending on the embodiment.

In the preferred form, the semantic tree evaluator 250, in step 314, determines a category to be applied at each node of the semantic tree instance. Since the semantic tree

instance is received from the SR application 210 as context free and representing all valid interpretations of the audio input, application of the context and a corresponding category at each node is necessary to achieve a single, correct linguistic result. This result serves as a response to a pending prompt by the application script 222'. Accordingly, also in step 314, the linguistic result is passed to application script 222'. Application script 222' determines its next action, e.g., send another prompt, as a function of the linguistic result.

As the session is conducted, the application script 222' need not access back-end servers for any reason. When the session is finished, for example, if a survey being administered by application script 222' is complete, the application script 222' may be deleted. The ActiveX objects remain resident at the SR system and may be reused by other application scripts downloaded to the SR system.

The invention may be embodied in other specific forms without departing from the spirit or central characteristics thereof. The present embodiments are therefore to be considered in all respects as illustrative and not restrictive, the scope of the invention being indicated by appending claims rather than by the foregoing description, and all changes that come within the meaning and range of equivalency of the claims are therefore intended to be embraced therein.
